Dextran is a significant class of polysaccharides, predominantly composed of numerous glucose molecules interlinked by specific glycosidic bonds, with α - 1,6 - glycosidic bonds taking the lead and a minor presence of α - 1,3 and α - 1,4 - glycosidic bonds, thus earning its name due to its dextrorotatory optical activity. It is typically obtained through the fermentation of sucrose by *Leuconostoc mesenteroides*. The resulting product appears as a white, amorphous solid, readily soluble in water, and the viscosity of its aqueous solution varies according to its molecular weight. Dextran derivatives, on the other hand, are compounds crafted by chemically modifying the hydroxyl groups of the glucose units in dextran via esterification, etherification, or other methods. These derivatives markedly differ from the parent dextran in their properties.
