## Abstracts

The global Digital Flexographic Printing Plates market size is expected to reach \$ 1470 million by 2029, rising at a market growth of 4.8% CAGR during the forecast period (2023-2029).

Most flexo plates today are exposed using direct 'computer-to-plate' technology (CTP). In this case, the unexposed film negative is supplied pre-laminated onto the photopolymer sheet, so that both layers can be exposed in the same piece of equipment.

A laser is directed by a computer to first expose the negative layer, after which the photopolymer is then exposed to the UVA light source. This exposure technique produces a superior quality plate, compared with the traditional method. The exposed plate is then processed, using the washout method described above.

Flexographic printing plate is flexible Digital Flexographic Plates plates, used in flexo printing to transfer ink & images to a flexible substrate, such as paper or film.

Flexographic printing plates are flexible photopolymer plates, used in flexo printing to transfer ink & images to a flexible substrate, such as paper or film. The printing plates are a critical element of the flexographic printing process and the quality of the printed image is largely dependant on the quality of the flexo plates used.

The flexo process itself is well known for adapting to print onto all types of flexible substrates and the plates can be used & re-used over millions of impressions.

The plate surface is the only area that comes into contact with the substrate after the ink

is applied to the plate. The etched or relieved areas do not contact the ink. Originally, flexo plates were made from rubber, but are today made from photopolymer material in sheet form – which differentiates them from the fixed metallic printing plates of offset printing. The plates are flexible enough to be wrapped around cylindrical print/plate rollers.
