## Abstracts

At the core of every DLP chipset is an array of highly reflective aluminum micromirrors, which is known as digital micromirror devices (DMD). DMD is an electronic input/optical output micro-electromechanical system (MEMS), which allows developers to perform high-speed, efficient and reliable spatial light modulation.

Using TI's semiconductor technology, each DMD contains up to 2 million independently controlled micromirrors (built on corresponding CMOS memory cells). During operation, the DMD controller loads a '1' or a '0' for each basic storage unit. Next, a mirror reset pulse is applied, which causes each micromirror to deviate electrostatically by approximately one hinge, thereby achieving a corresponding  $\pm 12^\circ$  state. Due to the resistance of the two spring thimble and the physical stop, the deviation angle of these two effective states is repeatable. In a projection system, the  $+12^\circ$  state corresponds to 'on' pixels, and the  $-12^\circ$  state corresponds to 'off' pixels. Grayscale graphics are created by programming the on/off duty cycle of each lens, and multiple light sources can be multiplexed to create RGB full-color images.

According to our (Global Info Research) latest study, the global DMD Chip market size was valued at USD million in 2022 and is forecast to a readjusted size of USD million by 2029 with a CAGR of % during review period.
