Abstracts

The Electrochemical Capacitance-Voltage (ECV) profiling technique is employed to measure the active carrier concentration profiles in semi-conductor layers.

The technique uses an electrolyte-semiconductor Schottky contact to create a depletion region, a region which is empty of conducting electrons and holes, but contain ionized donors and electrically active defects or traps. The depletion region with its ionized charges inside behaves like a capacitor. The measurement of the capacitance provides information of the doping and electrically active defect densities. Depth profiling is achieved by electrolytically etching the semiconductor between the capacitance measurements with no depth limitation.

According to our (Global Info Research) latest study, the global Electrochemical Capacitance Voltage Profiler market size was valued at USD million in 2022 and is forecast to a readjusted size of USD million by 2029 with a CAGR of % during review period.
