Abstracts

The global Eyeglasses Lenses Monomer market size is expected to reach \$ 3529 million by 2030, rising at a market growth of 6.2% CAGR during the forecast period (2024-2030).

The resin lens manufacturing industry is an industry driven by technological innovation. Resin monomers, optical additives (such as photosensitizers), key production equipment (such as coating machines) and other high-tech products involving materials, optics, automatic control and other fields are technically difficult. In recent years, as consumers have higher and higher requirements for lens quality and wearing experience, as well as the development of science and technology and people's continuous research on lens materials, the research and development of resin lenses has continued to make breakthroughs. Different types and different refractive index lens materials Have appeared.

The development process of my country's resin lens industry is slower than that of developed countries and regions such as the United States and Europe. As a result, cutting-edge technologies are basically controlled by foreign manufacturers, while domestic companies master the technology of large-scale industrial production. In recent years, a few companies have begun to get involved in the research, development and production of raw materials related to resin monomer materials. At present, some domestic manufacturers have begun to supply core raw materials needed for synthetic resin monomers.

Glasses lens materials refer to the materials used to make glasses lenses, mainly including glass, resin and PC.

The main raw material of glass lenses is optical glass, which has excellent optical properties, good light transmittance and mechanical and chemical properties, constant refractive index, and stable physical and chemical properties. Glass lenses have high surface hardness and are more resistant to wear and tear. However, due to their heavy weight and fragility, fewer and fewer glass lenses are used in recent years.

Resin is a hydrocarbon (hydrocarbon) secretion from plants, especially coniferous plants, and is valued for its other special chemical structures. Resin can be divided into two types: natural resin and synthetic resin. Resin lenses are lenses that are chemically synthesized using resin as raw material and processed and polished. Resin lenses are light in weight and more comfortable to wear; they have strong impact resistance, are not fragile and are safer; they also have good light transmittance; they are easy to reprocess and can meet special needs; coupled with the innovation and improvement of the coating process, resin lenses also have good Excellent wear resistance, it has become the mainstream lens on the market.

In addition, there are some special lens materials, such as photochromic lens materials, materials that can change color according to different changes in light. This material is usually composed of two different optical materials. When light enters, due to the different refractive index of the two materials, the light is scattered and reflected, thus changing the color of the lens.
