## Abstracts

The global Flocculant Chemicals market size is expected to reach \$ 4936.2 million by 2029, rising at a market growth of 4.8% CAGR during the forecast period (2023-2029).

Under the background of slower economy growth rate, companies face the higher risks of profit decline. Currently, flocculant market has a certain potential in Europe, USA and Japan. These areas demand are relatively stable. For developed countries, the market for flocculants is highly mature, and it seems unreasonable to try to get more growth. The market is driven mainly by fast-growing economies such as China and India. The large amount of sewage brought by developing countries' own industries or urbanization has created opportunities for the development of this industry. Flocculation is the process where a chemical agent (flocculant) is used to reduce the turbidity of a liquid by binding suspended particles in the liquid together to form larger particles (flocs) that are heavy enough to settle to the bottom of the liquid. There are mainly three types of flocculants: Inorganic Flocculant, Organic Flocculant, and Composite Flocculant and Microbial Flocculant etc.. Subdivision into the specific product included: AS, PAC, PFS and PAM etc. In addition, most inorganic flocculants are considered as coagulants and flocculants at the same time. For this, there is no significant difference in the use of inorganic flocculants.

Flocculants are chemicals that promote flocculation by causing colloids and other suspended particles in liquids to aggregate, forming a floc. They are used in water treatment processes to improve the sedimentation or filterability of small particles. Flocculant, or pool floc, is a chemical that you add to your pool when other methods of clearing it up aren't working. The flocculants clump together floating particles in the water that are too small and light to sink to the bottom to be vacuumed up. Flocculants also help remove dirt from water.
