Abstracts

Flocculant and coagulant are important chemicals used in water and wastewater treatment processes for solids removal, water clarification, lime softening, sludge thickening, and solids dewatering.

Flocculation is the process where a chemical agent (flocculant) is used to reduce the turbidity of a liquid by binding suspended particles in the liquid together to form larger particles (flocs) that are heavy enough to settle to the bottom of the liquid.

Coagulation is the process by which particles become destabilized and begin to clump together. Coagulation is an essential component in water treatment operations. Evaluation and optimization of the coagulation/rapid mixing step of the water treatment process includes a variety of aspects. Flocculants gather the destabilized particles together and cause them to agglomerate and drop out of solution.
