Abstracts

The global Heated Absolute Pressure Sensor market size is expected to reach \$ million by 2029, rising at a market growth of % CAGR during the forecast period (2023-2029).

The heated absolute pressure sensor is a sensor used to measure absolute pressure in the environment. It compensates for the effects of temperature by heating the sensor element to improve the accuracy and stability of the measurement. The working principle of heated absolute pressure sensors is to compensate for the influence of temperature changes on the measurement results by heating the temperature difference between the sensor element and the measuring element. A heating element inside the sensor continuously heats the sensor element to maintain it at a constant temperature, while the measuring element measures pressure changes in the environment. By measuring the temperature difference between the sensor element and the measuring element, the absolute pressure in the environment can be determined. Heated absolute pressure sensors usually have the following characteristics: 1. High accuracy: The sensor improves the accuracy of measurement through heating and temperature compensation, and can provide accurate absolute pressure measurement results. 2. Temperature compensation: The sensor has a built-in temperature sensor that can measure the ambient temperature in real time and perform temperature compensation through an internal algorithm to eliminate the impact of temperature changes on the measurement results. 3. Wide measurement range: The sensor can cover a large pressure range, ranging from a few pascals to several megapascals, and is suitable for the pressure measurement needs of different application scenarios. 4. High reliability: The sensor adopts high-quality materials and structural design, has high anti-interference ability and stability, and can operate stably for a long time in harsh environments.
