According to our (Global Info Research) latest study, the global HIV Vaccine market size was valued at US\$ million in 2025 and is forecast to a readjusted size of US\$ million by 2032 with a CAGR of %during review period.

AIDS, or Acquired Immunodeficiency Syndrome (AIDS), is caused by the human immunodeficiency virus (HIV), also known as the AIDS virus. HIV can specifically attack and destroy human immune cells, causing damage to the human immune system, gradual loss of related immune functions, and gradually becoming the target of many diseases, leading to various serious opportunistic infections, tumors, etc. At present, AIDS has become an important public health issue that seriously threatens the health of people around the world. In 1981, doctors discovered the first known case of HIV in the United States, and since then, more than 40 million people have died from the virus. According to data from the United Nations AIDS Program, men who have sex with men, female sex workers and their clients, transgender people, and people who inject drugs are at high risk. The virus is transmitted through the exchange of body fluids of infected people, such as blood, semen, and vaginal excrement. The most common is during unprotected sex, pregnancy and childbirth, transfusion of contaminated blood, or sharing of hypodermic needles. The human body cannot completely eliminate HIV. Therefore, once infected with the virus, an individual will remain HIV positive for life. However, through antiretroviral therapy (ART) drug treatment, HIV can be controlled, its progression can be significantly slowed, and gradually become a 'chronic disease'. In theory, before the emergence of curative drugs, AIDS patients need to take medication for life. Although there are relatively many existing antiviral therapies, they all have a clear disadvantage: long taking cycles and short intervals. Once the medication is stopped or missed, it will lead to the deterioration of AIDS; and long-term medication may also cause problems such as drug resistance and liver damage. Historically,

vaccines have been the most effective means of preventing or even eradicating infectious diseases. They can safely and cost-effectively prevent disease, disability and death. HIV vaccine is a potential vaccine that can be both a preventive vaccine and a therapeutic vaccine, meaning that it can protect individuals from HIV infection and treat HIV-infected people. In theory, it can have a significant impact on transmission rates and help control epidemics.
