According to our (Global Info Research) latest study, the global Humanoid Robots market size was valued at US\$ 1195 million in 2025 and is forecast to a readjusted size of US\$ 40913 million by 2032 with a CAGR of 49.5% during review period.

Among humanoid robots, there are two main categories based on their morphology: bipedal humanoid robots and wheeled humanoid robots. Bipedal robots are a type of bionic robot, whose core imitates the structure of human lower limbs. They drive joint movement through a servo system (composed of motors, drivers and encoders) to form a closed-loop control: the driver sends a command signal to the motor, and after the motor executes the action, the encoder feeds back parameters such as position and speed to the driver in real time, and achieves precise motion control through dynamic adjustment. This design gives bipedal robots highly bionic dynamic characteristics, enabling them to have multiple degrees of freedom, flexibility of movement and adaptability to complex environments (such as walking up and down stairs and on uneven roads), but they also face stability challenges due to the high complexity of mechanical structure and control algorithm. Wheeled humanoid robots use wheel hub or omnidirectional wheel drive, combined with chassis steering mechanism (such as differential steering or steering wheel control) to achieve movement. Its advantages are simple structure, high motion efficiency, intuitive control logic, and can stably complete basic functions such as straight-line travel and turning, but it is limited by the physical characteristics of the wheeled structure and is difficult to cope with unstructured terrain such as steps and slopes. The two types of forms serve different scenarios: bipedal robots are more suitable for interaction and service scenarios that require anthropomorphic movements, while wheeled robots tend to be more efficient in moving and performing basic tasks in flat environments.

As the core carrier for humanoid robots to realize anthropomorphic functions, the limb system integrates cutting-edge technologies from multiple disciplines, such as mechanical engineering, material science, and electronic control. Its technical architecture is mainly composed of actuators, sensor systems, power supplies, and new materials. The collaborative innovation of each subsystem is driving the industry into a stage of explosive growth.

1. The actuator includes rotary actuator, linear actuator and end effector.

The core components of rotary actuator: frameless torque motor, planetary reducer and harmonic reducer, etc. Using the golden combination of 'motor + reducer', there are currently two mainstream technical routes: one is to use a high-torque motor with a low-reduction ratio planetary reducer. This solution has certain cost advantages and is a relatively economical solution, suitable for scenes with low precision requirements; the other is to integrate a high-speed low-torque motor + harmonic reducer. This solution is more expensive, but the robot's motion control is relatively accurate. In the field of precision reducers, the current suppliers that can provide solutions for humanoid robots include Harmonic Drive, Nabtesco, Leader Harmonious Drive Systems Co., Ltd, Zhejiang Laifual Drive Co., Ltd, Nidec Drive Technology, Shenzhen With Sichuan Technology Co., Ltd, Shenzhen PICEA Motion Technology, etc.

Linear actuators are mainly components that realize linear motion such as extension, such as lead screws. A humanoid robot may use 2-3 types of lead screws, such as the Tesla Optimus, which uses trapezoidal lead screws and planetary roller screws. The cost and performance of each type are quite different, among which planetary roller screws are the mainstream direction in the future, but the current cost is relatively high.

The end effector is mainly a dexterous hand. According to the number of fingers, there are two fingers, three fingers, four fingers and five fingers. Technical miniaturization and multi-degree of freedom are the key trends in the future. The characteristics of multi-degree of freedom enable the human hand to flexibly complete various grasping tasks and delicate and complex operations.

2. In terms of humanoid robot sensors, there are many types involved, including inertial measurement units (IMUs), visual sensors, tactile sensors, six-dimensional force sensors, joint torque sensors, etc. Their core functions are mainly to achieve complex perception functions. Technically, high precision, multi-dimensionality, and high integration are the mainstream trends in the future.

3. In terms of robot materials, lightweight materials are the focus. With lightweight materials, humanoid robots have higher flexibility and work efficiency, and also ensure the safety of the human-robot collaboration process. For example, the Tesla Optimus G2 humanoid robot uses PEEK material to reduce weight, and its walking speed is 30% higher than that of the Optimus G1.

4. Judging from the current market situation, most humanoid robots have only realized basic interactive capabilities such as walking, running, and jumping, and the realization of specific functions in specific scenarios is still under exploration. In the future, the direction of humanoid robots is to replace or assist humans in completing various tasks, and will play an important role in various application scenarios.

5. Globally, humanoid robot suppliers mainly come from China, the United States and Japan, of which Chinese companies account for 51% and the United States accounts for about 23%. In terms of market competition, the mainstream suppliers are still robot companies, such as Unitree Robotics and UBTECH Robotics Inc in China; Agility Robotics, Boston Dynamics (Hyundai), Figure AI in the United States, etc. In addition, there are some cross-border companies, such as Tesla, Xiaomi, Xiaopeng, etc.

6. The current humanoid robot industry has crossed the technological embryonic stage and officially entered a period of rapid expansion. This high-speed expansion trend is triggering a deep reconstruction of the industrial structure, showing a typical 'dual-track competition' feature:

In the mainstream track, leading companies with full-stack technology integration capabilities are accelerating the construction of competitive barriers. Such companies often hold three core chips - motion control algorithms that have undergone iterative verification, vertically integrated supply chain systems, and large-scale manufacturing capabilities. They continuously optimize the synergistic efficiency of reducers, motors, and drivers, compressing the BOM cost of the entire machine to below the industry average, forming a Matthew effect in the general humanoid robot market. In the segmented track, start-ups and cross-border players are competing with the strategy of 'breaking through the segmented market'. Such companies focus on specific scenario needs: such as medical assistance, educational companionship scenarios, etc. This differentiation trend is essentially the result of the resonance between technology maturity and market demand, and the market will eventually present a 'pyramid' structure.
