Hydroxyapatite chromatography resin is a specialized type of chromatographic medium widely used in biochemistry and biotechnology for the separation and purification of biomolecules. It consists of a matrix composed of hydroxyapatite, a calcium phosphate mineral with the chemical formula $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$, which is immobilized onto a suitable resin support. The unique structure of hydroxyapatite provides two types of interaction sites: calcium ions on the surface can interact with negatively charged groups on biomolecules through cationic exchange, while the phosphate groups can engage in interactions with positively charged groups or groups with specific polar characteristics on the biomolecules. This dual-mode interaction allows for the selective binding and separation of a diverse range of biomolecules such as proteins, nucleic acids, and enzymes. Hydroxyapatite chromatography resin is typically packed into a column, and a sample containing the mixture of biomolecules is passed through it. Different biomolecules will bind to the resin with varying affinities based on their charge and structural features, and can then be eluted in a sequential manner by adjusting the conditions of the mobile phase, such as the pH, ionic strength, or the presence of specific additives. Through this process, it enables the effective purification and isolation

of target biomolecules from complex biological samples, playing a crucial role in research, drug development, and bioprocessing applications.
