According to our (Global Info Research) latest study, the global Industrial Overrunning Clutches market size was valued at USD million in 2023 and is forecast to a readjusted size of USD million by 2030 with a CAGR of % during review period.

In mechanical or automotive engineering, a freewheel or overrunning clutch is a device in a transmission that disengages the driveshaftfrom the driven shaft when the driven shaft rotates faster than the driveshaft.

In agricultural equipment an overrunning clutch is typically used on hay balers and other equipment with a high inertial load, particularly when used in conjunction with a tractor without a live power take-off (PTO). Without a live PTO, a high inertial load can cause the tractor to continue to move forward even when the foot clutch is depressed, creating an unsafe condition. A freewheel assembly is also widely used on engine starters as a kind of protective device. Starter motors usually need to spin at 3,000 RPM to get the engine to turn over. When the key is held in the start position for any amount of time after the engine has started, the starter can not spin fast enough to keep up with the flywheel. Freewheels are also used in rotorcraft. As a bicycle's wheels need to be able to rotate faster than the pedals, so do a rotorcraft's blades need to be able to spin faster than its drive engines.
