## Abstracts

The global InSAR Satellite Monitoring market size is expected to reach \$ 930 million by 2032, rising at a market growth of 10.7% CAGR during the forecast period (2026-2032).

Interferometric synthetic aperture radar, abbreviated InSAR, is a radar technique used in geodesy and remote sensing. This geodetic method uses two or more synthetic aperture radar (SAR) images to generate maps of surface deformation or digital elevation, using differences in the phase of the waves returning to the satellite or aircraft. The technique can potentially measure millimetre-scale changes in deformation over spans of days to years. It has applications for geophysical monitoring of natural hazards, for example earthquakes, volcanoes and landslides, and in structural engineering, in particular monitoring of subsidence and structural stability.

InSAR services have been widely applied across various sectors of the national economy.

1. Infrastructure Safety: Large-scale, non-contact health monitoring of bridges, dams, high-speed railways, subways, oil and gas pipelines, and power facilities to promptly detect potential safety hazards such as subsidence and tilting.
2. Geological Disaster Prevention: Identifying and monitoring landslides, ground subsidence, mining subsidence, and ground fissures to provide data support for disaster early warning.
3. Urban Planning and Management: Monitoring regional ground subsidence caused by groundwater extraction and engineering construction in cities, providing scientific basis for urban planning, land development, and building safety.

4. Resource Exploration and Monitoring: Monitoring surface deformation caused by mining activities in industries such as oil and gas and mining to ensure safe production.

5. Earth Science Research: Applied to the study of geodynamic processes such as earthquakes, volcanic activity, glacial movement, and plate tectonics.
