Abstracts

According to our (Global Info Research) latest study, the global Interdigital IDT Filter market size was valued at US$ million in 2025 and is forecast to a readjusted size of US$ million by 2032 with a CAGR of %during review period.

Interdigital IDT filters are filters that use interdigital transducers (IDTs) as key components. IDTs are made by depositing a layer of metal film on a piezoelectric substrate and obtaining a row of crossed electrodes by photolithography. When an alternating electric field is loaded on these crossed electrodes, surface acoustic waves (SAWs) are generated on the piezoelectric substrate through the inverse piezoelectric effect. These surface acoustic waves are then used to filter signals. The working principle of interdigital IDT filters is mainly based on the propagation and filtering characteristics of surface acoustic waves. When a high-frequency voltage is applied to both ends of the IDT, a potential difference is generated between adjacent fingers, thereby forming a high-frequency electric field on the surface of the piezoelectric substrate and in the nearby space. These electric fields further generate high-frequency strains inside the piezoelectric substrate, thereby exciting surface acoustic waves. These surface acoustic waves propagate on the surface of the piezoelectric substrate and achieve selective filtering of signal frequencies through specific design.

As a specific type of filter, interdigital IDT filters play an important role in RF front-end technology, especially in the field of wireless communications. Interdigital IDT filters are widely used in wireless communication systems, such as mobile phones, base stations, and IoT devices. They improve communication quality by optimizing signal frequency selection performance. In 5G and future communication technologies, the demand for interdigital IDT filters will increase further due to the increase in frequency bands and
