According to our (Global Info Research) latest study, the global Interferon Therapy of Chronic Hepatitis B market size was valued at US\$ million in 2025 and is forecast to a readjusted size of US\$ million by 2032 with a CAGR of %during review period.

Interferon therapy for chronic hepatitis B involves the use of interferon, particularly pegylated interferon-alpha, which is administered via injection and works by stimulating the immune system to target and destroy HBV-infected liver cells. Unlike antiviral medications that primarily suppress viral replication, interferon therapy can potentially lead to a sustained viral response and long-term remission after treatment ends. It is generally used for patients with chronic hepatitis B who have not achieved adequate results with antiviral drugs or who are suitable for its potential benefits.

Interferon therapy for chronic hepatitis B has seen evolving trends over the past few years, reflecting advancements in treatment protocols and a deeper understanding of the disease. Historically, interferon-alpha was used as a primary treatment option, but its use was limited by side effects and variable efficacy. The development of pegylated interferon-alpha, a modified form with extended action, has marked a significant improvement. Pegylated interferon offers a more convenient dosing schedule (usually weekly) and has been shown to improve treatment adherence and outcomes. This form of interferon has become a key component in managing chronic hepatitis B, particularly for patients who may not respond adequately to conventional antiviral therapies.

Recent trends in interferon therapy involve refining patient selection criteria and combining interferon with other therapeutic approaches to enhance efficacy. Ongoing research focuses on identifying biomarkers that predict which patients are most likely to

benefit from interferon therapy, thus personalizing treatment and minimizing unnecessary side effects. Additionally, combination therapies involving interferon and novel antiviral agents are being explored to achieve better viral suppression and long-term remission. This approach aims to address the limitations of monotherapy by leveraging the strengths of both interferon and newer antiviral drugs.

Looking forward, the development of interferon therapy for chronic hepatitis B is expected to continue evolving with advancements in drug formulations and a better understanding of patient-specific factors. Research is also exploring the potential of interferon-based therapies in combination with emerging treatments such as immune modulators and novel antiviral agents. These developments aim to optimize treatment outcomes, reduce side effects, and provide more effective options for managing chronic hepatitis B, ultimately improving patient care and long-term health outcomes.
