Abstracts

The global Isolated Resistor Network market size is expected to reach \$ million by 2029, rising at a market growth of % CAGR during the forecast period (2023-2029).

An isolated resistor network is a circuit configuration used to isolate signals, prevent interference, protect equipment, or perform a specific function in an electrical system. It usually consists of multiple resistors, which are isolated from each other and do not touch each other, so as to avoid mutual interference of signals. Isolated resistor networks typically consist of two parts: an input and an output. The input terminal receives the input signal, and the output terminal outputs the signal processed by the resistor network. The input and output are usually electrically isolated, such as optocouplers, transformers, or magnetic isolators, to prevent signal interference and pass current. Isolated resistor networks can be used in a variety of applications, including isolation measurement, isolation amplification, isolation regulation, isolation isolation, and more. For example, in industrial control systems, isolated resistor networks can be used to isolate input and output signals, thereby ensuring the stability and reliability of signal transmission, preventing potential problems caused by noise, interference, and status differences. Additionally, isolated resistor networks can be used to create isolation between different potentials to protect sensitive electronics from high voltages or high currents.
