Abstracts

The global Isostearic Acid for Lubricants market size is expected to reach \$ 252 million by 2032, rising at a market growth of 5.5% CAGR during the forecast period (2026-2032).

Global sales of isostearic acid for lubricants reached 22,800 tons in 2025, with an average price of US\$7,347 per ton.

Isostearic acid for lubricants is a type of synthetic base oil or functional additive primarily composed of branched C18 fatty acids. It is produced through the catalytic hydrogenation and isomerization reactions of natural unsaturated fatty acids (such as oleic acid and ricinoleic acid). Its molecular structure is a methyl-branched octadecanoic acid, possessing unique properties such as a low pour point, high viscosity index, and excellent thermal oxidative stability and shear stability. Compared to traditional straight-chain fatty acids, its branched structure endows it with the ability to remain liquid at low temperatures, while also providing good lubricity and metal surface adsorption. In the lubricant industry, isostearic acid can be used alone as a synthetic base oil, or it can be used to prepare isostearate lubricants through esterification, or added to mineral or synthetic oils as an oiliness agent or friction modifier. It is widely used in high-end lubrication applications such as automotive engine oils, industrial gear oils, compressor oils, and metalworking fluids.

The raw material system for lubricant-grade isostearic acid uses natural vegetable oils as the core starting material, mainly derived from renewable resources such as castor oil (primarily produced in India and China), palm oil (Southeast Asia), and rapeseed oil (Europe and Canada). Unsaturated fatty acids (such as oleic acid and ricinoleic acid) are converted into branched isostearic acid through a high-pressure hydrogenation-isomerization process. During production, the vegetable oil is first hydrogenated to

saturation under the action of a nickel or precious metal catalyst, and then undergoes skeletal isomerization on an acidic catalyst (such as a molecular sieve) to form C18 fatty acids with methyl branches. Finally, it is purified to lubricant-grade specifications (acid value typically controlled at 190-200 mgKOH/g, color 60%), but its production costs are correspondingly 20-30% higher.
