Kaposi's sarcoma (KS) is a type of cancer that can form masses in the skin, lymph nodes, or other organs. The skin lesions are usually purple in color. They can occur singularly, in a limited area, or be widespread. It may worsen either gradually or quickly. Lesions may be flat or raised.

Four sub-types are described: classic, endemic, immunosuppression therapy-related, and epidemic. Classic KS tends to affect older men, be slow growing, and affect the legs. Endemic KS occurs in young adult males in Africa and can be more aggressive. Immunosuppression therapy-related KS generally occurs in people following organ transplantation and mostly affects the skin. Epidemic KS occurs in people with AIDS and many parts of the body can be affected. The diagnosis is by tissue biopsy while the extent of disease may be determined by medical imaging.
