## Abstracts

The global Leaded Power Inductor market size is expected to reach \$ million by 2029, rising at a market growth of % CAGR during the forecast period (2023-2029).

Leaded Power Inductor (Leaded Power Inductor) is a type of inductor that is commonly used in applications such as power electronics, power modules, DC-DC converters, and linear regulators. They usually have leads (or called pins) as the connection method, hence the name lead type power inductors. Leaded power inductors are mainly used to store and release electrical energy and limit the rate of change of current. They usually use a coil-shaped inductive element to control the current through the self-inductance and mutual inductance in the coil. Features of leaded power inductors include higher current carrying capability, lower resistance, higher inductance, and lower DC resistance (DCR). Leaded power inductors typically have standardized lead spacing and dimensions for ease of mounting and connection to circuit boards. Leads are typically used for solder connections to circuit boards, but can also be used for connections to other components. Leaded power inductors are usually mounted on a printed circuit board (PCB), and are connected to the pads on the circuit board by soldering the leads to play an inductive role in the circuit. The parameters of lead-type power inductors include inductance value, rated current, DC resistance (DCR), frequency response, temperature characteristics, etc. These parameters need to select the appropriate model and specification according to the needs of specific applications. When designing power circuits and power electronic systems, lead-type power inductors are usually used for filtering, step-down, step-up, current limiting, voltage stabilization, etc., to ensure the normal operation and stable performance of the circuit.
