Abstracts

The global Lithium Supplement Additive market size is expected to reach \$ 692 million by 2032, rising at a market growth of 29.3% CAGR during the forecast period (2026-2032).

Lithium Supplement Additive refers to adding lithium to the interior of a lithium battery before its operation to supplement lithium ions. This means adding lithium to the electrode material through pre lithiation, solving problems such as low first cycle efficiency, low first cycle efficiency, and poor cycle life of the negative electrode of a lithium battery. Lithium supplements are an effective method to improve the capacity and energy density of lithium batteries. In recent years, with the development of new energy vehicles, consumer electronics, and other industries, the scale of the lithium battery industry has been continuously expanding, and the demand for lithium supplements in the market has also been released. In 2025, global Lithium Supplement Additive sales reached approximately 1,920 tons, with an average price of 60 US\$/Kg. Currently, lithium supplementation methods are divided into two types: anode lithium supplementation and cathode lithium supplementation. Anode lithium supplementation includes approaches such as lithium foil supplementation, lithium powder supplementation, lithiated silicon powder supplementation, and electrolyte lithium salt aqueous solution supplementation. However, anode lithium supplementation still faces significant challenges related to battery manufacturing processes: incompatibility of metallic lithium with production environments, conventional solvents, binders, and heat treatment procedures make the path for anode lithium supplementation difficult and full of obstacles. As an alternative technical route, many lithium supplementation additives targeting cathode materials have entered the research scope. Compared to the complex and high-investment anode supplementation, cathode lithium supplementation is much simpler: typically, a small amount of high-capacity material is added during the cathode slurry mixing process; during charging, Li⁺ ions are released from the high-capacity

material to compensate for the irreversible capacity loss during the first charge-discharge cycle. Cathode lithium supplementation has the greatest industrial application potential due to its high safety and the fact that it does not require changes to existing battery manufacturing processes. Currently, the main materials used as cathode lithium supplementation additives include lithium-rich compounds, conversion reaction-based nanocomposites, and binary lithium compounds.
