Abstracts

According to our (Global Info Research) latest study, the global Magnetic Bead Cell Separation Products market size was valued at USD million in 2023 and is forecast to a readjusted size of USD million by 2030 with a CAGR of % during review period.

Magnetic Bead Cell Separation, also known as immunomagnetic cell separation or magnetic cell sorting, involves targeting cells for selection or depletion using antibodies or ligands directed against specific cell surface antigens. Labeled cells are cross-linked to magnetic particles, also known as magnetic beads, that can be immobilized once an electromagnetic field is applied. Due to its speed and simplicity, magnetic cell separation is one of the most commonly used methods by which scientists isolate highly purified populations of specific cell subsets.

There are two different formats for performing immunomagnetic separation: column-based and column-free.

Column-based magnetic cell separation techniques involve passing a sample previously labeled with magnetic particles through a column matrix within a magnetic field. The column is filled with ferromagnetic spheres that become magnetized in the applied magnetic field, creating a localized magnetic field that can immobilize the magnetic particles within the sample. When positive selection is used, non-magnetically-labeled, non-target cells can pass through the column while magnetically-labeled, target cells are retained within the column. Upon removing the external magnetic field, the target cells can be collected by pushing buffer through the column.

While commonly-used, column-based magnetic cell isolation protocols can sometimes

be costly, complicated, laborious, and time-consuming, requiring multiple washes to avoid contamination between separations and the use of new columns for each experiment. In addition, it's not uncommon for columns to become clogged, risking the loss of precious samples, especially when working with tissue samples that contain a significant amounts of debris.

Column-free magnetic cell separation techniques involve placing a tube filled with a magnetically-labeled sample within a magnetic field. The magnetically-labeled target cells will migrate towards the magnet and will be immobilized at the sides of the tube. The unlabeled cells in suspension can then be poured or pipetted off to separate them from the labeled cells. Upon removing the tube from the magnet, the labeled cells are released from the sides of the tube. If a positive selection protocol is used, the labeled cells are the cells of interest and can be resuspended in buffer for immediate use in downstream applications.
