Abstracts

The global Molecular Spectrometer Sensor market size is expected to reach \$ million by 2030, rising at a market growth of % CAGR during the forecast period (2024-2030).

Emission and absorption spectra formed by transitions between molecular energy levels. Molecular spectra are very rich and can be divided into pure rotational spectra, vibrational-rotational spectral bands, and electronic spectral bands. Pure rotational spectra of molecules are generated by transitions between rotational energy levels of molecules, and are distributed in the far-infrared band. Absorption spectra are usually mainly observed; vibration-rotation spectral bands are generated by transitions between rotational energy levels at different vibrational energy levels, and are Some dense spectral lines are distributed in the near-infrared band, and absorption spectra are usually mainly observed; electronic spectral bands are generated by transitions between different vibrations and different rotational energy levels in different electronic states, and can be divided into many bands, distributed in the visible or ultraviolet Band, observable emission spectrum. Since non-polar molecules do not have an electric dipole moment, they do not have rotational spectra and vibration-rotational spectral bands. Only polar molecules have such spectral bands.
