Abstracts

Non-invasive traumatic brain injury monitoring devices are used to continuously monitor intracranial pressure (ICP) through a probe mounted on the forehead. Although the skull is a closed, rigid structure, interrogation using infrared light provides a potential 'window' for monitoring cerebral haemodynamics. The probe contains an infrared light source that illuminates deep brain tissue in the frontal lobe, while a photodetector in the probe detects backscattered light modulated by the pulsation of the cerebral arteries. Changes in pressure around the cerebral arteries affect the pattern of the recorded light pulses, so analysis of the acquired signal using appropriate algorithms will enable the calculation of a non-invasive ICP (nICP) that can be displayed continuously to the clinician.
