Collectors are reagents used in mineral processing and flotation processes. They can change the hydrophilicity and hydrophobicity of the surface of mineral particles, making specific mineral particles hydrophobic and easy to combine with bubbles, thereby achieving separation of minerals from gangue. The working principle of collectors is to make the surface of target minerals affinity with bubbles, while non-target minerals remain hydrophilic, thereby achieving effective separation and enrichment during the flotation process. Common collectors include xanthate, black medicine and fatty acids, which are used in the flotation process of different types of minerals, such as metallic minerals, non-metallic minerals, etc.

The importance of collectors in the mineral processing process cannot be ignored. In the flotation process, it helps to achieve the effective separation of minerals and waste rocks by selectively changing the chemical properties of the mineral surface. With the decline in the grade of mineral resources and the complexity of ore composition, the research and development and optimization of collectors have become more critical. Collectors in modern mineral processing processes must not only have efficient collection capabilities, but also meet environmental protection and low toxicity

requirements to reduce the impact on the environment. In the future, green and sustainable collector technology will become an important trend in the development of the mining industry, driving the mineral processing industry to develop in a more environmentally friendly and efficient direction.
