Abstracts

The global Oxygen Plasma Degumming Machine market size is expected to reach \$ million by 2029, rising at a market growth of % CAGR during the forecast period (2023-2029).

Oxygen plasma degumming machine typically use capacitively coupled plasma parallel plate reactors. In the parallel electrode reactor, the reactive ion etching chamber adopts an asymmetric design with a small cathode area and a large anode area, and the etched objects are placed on the electrodes with a small area. Under the action of thermal motion generated by radio frequency power supply, negatively charged free electrons reach the cathode due to their small mass and fast moving speed. Positive ions cannot reach the cathode at the same time due to their large mass and slow speed, thus forming a negatively charged sheath near the cathode. Accelerated by the sheath, positive ions bombard the surface of the silicon wafer vertically to promote chemical reactions on the surface and separation of reaction products, resulting in a high etch rate. The ion bombardment of plasma strippers also enables anisotropic etching to achieve the same principles of plasma strippers and plasma etching. The difference lies in the type of reactive gas and the method of excitation of the plasma.
