Abstracts

According to our (Global Info Research) latest study, the global Parallel Seam Sealer System market size was valued at USD million in 2022 and is forecast to a readjusted size of USD million by 2029 with a CAGR of % during review period.

Parallel Seam Sealer System is mainly used to package integrated circuit chips. The system of parallel sealing welding system is mainly composed of two parts: upper computer (pc) and lower computer (single chip microcomputer). The software of upper computer (pc) is developed by visual programming language vb6.0. mscomm control is used to complete the data communication between pc and single chip microcomputer, and transmit control information, state information and welding parameters. The humanization of welding is realized with the ability of vb6.0 to operate various databases. The lower computer (MCU) receives the command sent by the pc through the serial interface, starts the work program, controls 6 stepper motors (including two x axis, one y axis, two z axis, and one rotating ? axis), converts the angular displacement of the motor into linear displacement through the lead screw, drives the welding electrode to run according to the designed track, and transmits the current operating status to the pc in real time.

Parallel Seam Sealer System can heat and vacuum the sealing device, thereby reducing the humidity and oxygen molecule content in the cavity. After packaging, the chip inside the cavity is not easy to be oxidized, so that the chip is not damaged by external factors and has a protective effect on the chip, and does not affect the normal operation of the chip due to changes in external conditions. In the seam welding process to fill with protective gas nitrogen (protective effect on the device), the pressure is similar to an atmospheric pressure, which is conducive to the balance of internal and

external pressure in the use process, but also conducive to personnel operation, so that the device under long-term work, not due to internal and external pressure difference and make the shell separated. After packaging, the chip has a convenient and reliable electrical connection with the external system through the external lead wire (or called pin). The heat generated by the chip during work is dispersed through the package shell, so as to ensure that the chip temperature is kept under the maximum limit. Parallel seam welding can also be welded to ceramic tube base (with a metallized layer), glass tube base (with a metallized layer) and metal tube base. In the operation process, many are mechanized, which not only reduces the burden of the operator, but also makes the package more stable, and the yield is greatly improved.
