Abstracts

According to our latest research, the global PET Enzymatic Depolymerization market size will reach USD million in 2031, growing at a CAGR of %over the analysis period.

PET enzymatic depolymerization is a sustainable process that uses specific enzymes to break down polyethylene terephthalate (PET), a common plastic, into its monomeric components. Unlike traditional recycling methods, which involve high temperatures and chemicals, enzymatic depolymerization leverages naturally occurring or engineered enzymes to catalyze the hydrolysis of PET polymers into their constituent monomers, such as terephthalic acid and ethylene glycol. This approach offers a more energy-efficient and environmentally friendly alternative to mechanical recycling or chemical processes, as it operates under milder conditions and can potentially yield higher-quality recycled materials. By enabling the recovery and reuse of PET at a molecular level, enzymatic depolymerization supports circular economy goals and reduces plastic waste in the environment.
