Abstracts

The global Polyimide Raw Materials market size is expected to reach \$ 2420 million by 2032, rising at a market growth of 7.1% CAGR during the forecast period (2026-2032). Polyimide raw materials are the chemical building blocks and processing inputs used to manufacture polyimide (PI) resins, films, and coatings. The core monomers are typically an aromatic dianhydride (such as PMDA, BPDA, BTDA, ODPDA, or 6FDA) and an aromatic diamine (such as ODA, p-phenylenediamine, MDA, DDS, or MPDA/OPDA), which first react to form poly(amic acid) in a suitable solvent and then undergo imidization (usually by heat, or sometimes by chemical dehydrating agents) to become polyimide. In 2025, global Polyimide Raw Materials production reached approximately 136.5 K MT, with an average global market price of around US\$ 11022 per MT.

The polyimide (PI) raw materials market?dominated by aromatic dianhydrides (e.g., PMDA, BPDA, BTDA, ODPDA, 6FDA) and aromatic diamines (e.g., ODA, PPD, DDS, MDA, MPDA/OPDA)?is mainly driven by downstream growth in electronics and semiconductors (flex circuits/FPC, FCCL, insulation layers, advanced packaging, and high-temperature dielectrics), plus rising requirements for thin, high-reliability films and varnishes in compact consumer devices. Another big driver is electrification (EV motors, inverters, charging systems, and battery-related insulation), where heat resistance and dielectric strength matter; and in higher-value niches, demand is pulled by optical/transparent or low-CTE PI for flexible/foldable displays and by aerospace/defense applications that value thermal stability, flame resistance, and durability. Supply-side factors also shape demand: customers increasingly require high-purity/consistent lots, secure regional supply, and compliance with tightening environmental and worker-exposure rules (which can shift formulations and raise qualification barriers).

Upstream, PI monomers sit on top of aromatic petrochemical chains and a few specialty intermediates: many dianhydrides originate from alkylated aromatics that are oxidized

and dehydrated (with costs influenced by aromatics pricing, oxidants, energy, and waste handling), while fluorinated monomers (e.g., 6FDA-based systems) depend on the fluorochemicals value chain, which is more specialized and often more capacity-constrained. Aromatic diamines commonly rely on nitro-aromatic intermediates followed by catalytic hydrogenation (so nitric acid, hydrogen, catalysts, and hydrogenation capacity matter), and some key diamines (like MDA) are closely tied to aniline and formaldehyde economics and integration with adjacent value chains. Beyond monomers, practical PI production also depends heavily on polar aprotic solvents (e.g., NMP/DMAc/DMF) and process chemicals (imidization/curing aids and purification utilities), so solvent availability, regulatory constraints, and recycling infrastructure can materially impact delivered costs and qualification stability.
