## Abstracts

According to our (Global Info Research) latest study, the global Potentiometer market size was valued at USD 1766.4 million in 2023 and is forecast to a readjusted size of USD 2418.9 million by 2030 with a CAGR of 4.6% during review period.

There are three types of potentiometers that are used commonly: wire wound, carbon film and Plastic Film potentiometers. All these have been described below:

1) Wire wound potentiometers: This potentiometer comprises of several rounds of wire wound around the shaft of the non-conducting material. The turns of the coil are bonded together by an adhesive. In this case the slider, connected to the body whose displacement is to be measured, moves on the potentiometer track and it makes contacts with successive turns of the coil. In this case the wire between the two successive turns is not covered by the slider, which limits the resolution of the wire wound potentiometers. However, the larger the number of turns of the coil, more is the resolution of the coil. The resolution is measured as the reciprocal of the number of turns of the coil. This device has low noise and is mechanically rough and tough.

2) Carbon film potentiometers: The carbon film potentiometers are formed by depositing carbon composition ink on an insulating body, which in most of the cases is phenolic resin. This is one of the most commonly used materials for the pots that is quite cheap and has resolution better than the wire wound potentiometers. They have reasonable life and tolerable noise levels.

3) Plastic Film pots: These pots comprise of the specially impregnated plastic material having resistance characteristics that are controlled properly. These can be used for rotary as well as translational slider movements. They have very good life, resolution

better than the wire wound pots, and low noise.

In carbon film and the Plastic Film pots the resolution is limited by the grain size of the particles, hence their accuracy is very high. Their resolution can be as high as 10 rest to -4 and is usually limited only by the spring connected between the slider and the body whose motion is to be measured.
