Abstracts

Primary sclerosing cholangitis (PSC) is a condition causing long-term inflammation and scarring (fibrosis) of bile ducts in the liver. These ducts are tubes that allow the liquid (bile) produced by the liver to pass through the intestine allowing fat digestion. This disease predominantly affects men between the age of 25 and 40 years. The damage to the ducts causes accumulation of bile acids, essential components of bile to build up in the liver leading to liver tissue damage, portal hypertension (high blood pressure in the vessels connecting the liver and the gut), and liver failure, and may increase the risk of liver cancer.

Scope of the Report:

Requirement of providing affordable treatment, owing to high costs associated with liver transplantation coupled with increasing risk factors resulting in the development of serious disorders are major factors that are expected to increase the adoption of PSC drugs, in turn favoring market growth in the near future.
