## Abstracts

The global Radionuclide Scanning Services market size is expected to reach \$ 1794 million by 2032, rising at a market growth of 6.2% CAGR during the forecast period (2026-2032).

Radionuclide Scanning Services are a nuclear medicine diagnostic technology that uses radioactive tracers and specialized imaging equipment to non-invasively and visually assess the functional state of organs or tissues within a living organism. The core of this service lies in introducing radionuclide-labeled drugs into the body and then tracking their distribution and metabolic processes using an external detector, thereby reflecting abnormalities in blood perfusion, cell activity, and function of tissues and organs. Common types include SPECT scans and PET scans, and are widely used in fields such as oncology, cardiovascular, neurology, and endocrinology. Its core value lies in its ability to detect functional and metabolic abnormalities early, before changes in the anatomical structure of diseases occur, providing crucial information for accurate diagnosis and treatment decisions.

Global radionuclide scanning services prices vary significantly depending on the type of imaging and region. A routine SPECT bone scan costs approximately \$500-\$1500, while whole-body PET/CT imaging can reach \$2000-\$5000, and new probe-based scans such as PSMA-PET can cost as much as \$5000-\$10000. Radiopharmaceuticals constitute the largest portion of the cost structure, especially for short-half-life radionuclides produced by cyclotrons, such as  $^{18}\text{F}$ -FDG, which require local supply. Equipment depreciation and maintenance costs are high, and investments in PET/CT and cyclotrons are substantial. The cost of professional physicians and physicists is also significant. Gross profit margins exhibit clear stratification: routine SPECT bone scans, due to mature technology and intense competition, have a gross profit margin of

approximately 20%-40%; tumor PET/CT imaging, with its high clinical value and equipment barriers, can achieve a gross profit margin of 50%-70%; while new specific probe-based imaging, due to technological scarcity and high pricing, can achieve a gross profit margin exceeding 70%. However, constrained by health insurance payment policies, the overall industry's profitability is shaped by the stability of the radionuclide supply chain and equipment utilization rates.
