Abstracts

The global RF Frequency Multiplier market size is expected to reach \$ million by 2029, rising at a market growth of % CAGR during the forecast period (2023-2029).

RF frequency multipliers are nonlinear devices that produce an output signal with a frequency that is larger than the frequency of a corresponding input signal by a predetermined factor. RF frequency multipliers operate over a specific input frequency range and are able to suppress or reduce unwanted harmonics from the output signal. There are two basic types of devices: active and passive. Active RF multipliers produce an output signal with a power level that is larger than that of the input signal. The power level difference between the output signal and the input signal is called conversion gain, an amount that is measured in decibels (dB) and expressed as a positive number. Passive RF multipliers produce an output signal with a power level that is smaller than that of the input signal. The difference in power levels between the output signal and the input signal is called conversion loss, an amount that is expressed in decibels. Conversion loss is a negative number, but usually specified as an absolute value.
