Abstracts

According to our (Global Info Research) latest study, the global RLT Therapy market size was valued at US$ 3131 million in 2025 and is forecast to a readjusted size of US$ 6409 million by 2032 with a CAGR of 10.7% during review period.

Radioligand therapy is an advanced targeted cancer treatment method. Its core principle involves precisely delivering a cell-killing radionuclide to the lesion via a precisely designed "biological missile"—a ligand molecule that specifically recognizes markers on the surface of tumor cells. This design achieves cellular-level precision delivery, similar to internal radiation therapy: the radionuclide releases high-energy rays locally on the tumor, destroying the DNA of cancer cells while maximally protecting surrounding healthy tissue due to its extremely short radiation range. This therapy typically follows a "therapeutic approach," first using paired drugs with conjugated diagnostic radionuclides to perform imaging examinations to screen suitable patients and assess target expression levels, thus achieving truly personalized precision medicine.

Radioligand therapy shows great promise, evolving from a specialty therapy targeting a few specific targets into one of the core pillars of oncology. Its growth is driven by multiple factors: First, the range of targets is constantly expanding, moving from mature targets like PSMA and SSTR to new targets such as FAP and CDH6, covering a wider range of solid tumors beyond prostate cancer and neuroendocrine tumors. Second, radionuclide innovation is accelerating, with alpha radionuclide therapy becoming a research hotspot due to its stronger killing power and precision, and holding promise for treating more advanced or drug-resistant patients. In the future, "integrated diagnosis and treatment" will become the standard paradigm, driving precise pre-treatment screening and real-time monitoring of efficacy.
