Abstracts

According to our (Global Info Research) latest study, the global Server Analog IC market size was valued at US\$ 3961 million in 2025 and is forecast to a readjusted size of US\$ 13269 million by 2032 with a CAGR of 17.4% during review period.

In 2025, global sales of Server Analog IC reached approximately 760 million units, with an average market price of about USD 5.07 unit, an annual production capacity of roughly 780 million units, and an industry-average gross margin of approximately 60%.

Server Analog ICs are high-performance analog or mixed-signal integrated circuits designed to convert, regulate, distribute, protect, monitor and sequence electrical power within artificial-intelligence training servers, inference servers, GPU or custom-ASIC accelerator cards, server motherboards and rack-level power architectures. The principal product forms include analog and digital multiphase PWM controllers, smart power stages, DrMOS devices, integrated voltage regulators, point-of-load DC-DC converters, hot-swap controllers, electronic fuses, power-path controllers, PMBus-compatible digital power controllers, power sequencers and monitors, current-sensing ICs, isolated gate drivers, and integrated power ICs used in server power-supply units, battery-backup units and intermediate-bus converters. Key performance requirements include high output-current capability, rapid transient response, conversion efficiency, power density, telemetry accuracy, scalable phase control, processor-platform compatibility, thermal performance and system-level reliability. The research scope focuses on the power-management semiconductor chain extending from the server power input and board-level distribution network to the final voltage rails supplying AI processors, CPUs, high-bandwidth memory, networking devices, storage components and other computational loads.

Server Analog ICs should be viewed as an application-defined semiconductor segment created by the rapid increase in processor power, transient current and rack-level power density rather than as a simple extension of conventional server PMIC demand. AI GPUs, custom accelerators and high-bandwidth memory require multiple low-voltage, high-current rails that must respond rapidly to highly variable computational workloads. As a result, multiphase controllers, smart power stages, DrMOS devices, integrated voltage regulators, point-of-load converters and precision power-monitoring ICs increasingly influence achievable computing performance, energy efficiency and system reliability. The appropriate market boundary therefore covers the control, conversion, protection, sequencing and monitoring semiconductor chain between the server power input and the final computational load. It should not combine all analog ICs or all power semiconductors into a single category.

The global supply structure consists of several distinct layers. Large diversified analog and power-semiconductor companies offer broad portfolios spanning input protection, digital control, voltage regulation, current sensing and high-voltage power conversion. Specialist server-power suppliers concentrate on multiphase regulation, smart power stages and processor-specific Vcore solutions, while Taiwanese companies retain deep experience in PC, GPU and motherboard power architectures. Mainland Chinese entrants are extending capabilities developed in consumer charging, industrial power and general-purpose DC-DC products into server DrMOS, digital multiphase control, hot-swap protection and 48-volt conversion. Nevertheless, the number of companies with general power-management products is substantially larger than the number with confirmed AI-server production business. Qualification cycles, proprietary processor power protocols, transient-performance requirements, packaging know-how and hyperscale-customer reliability standards continue to limit rapid substitution.
