Abstracts

The global Single-Detector Gamma Camera market size is expected to reach \$ million by 2029, rising at a market growth of % CAGR during the forecast period (2023-2029).

The main consumer markets for Single-Detector Gamma Cameras are North America and the Asia Pacific region. With the gradual recovery of the global economy after the COVID-19 outbreak and the return of major economies to normal, the medical industry will see certain growth. As global medical standards continue to improve, more and more hospitals and clinics are able to carry out gamma camera examinations. As a result, the demand for Single-Detector Gamma Cameras will increase in the foreseeable future.

A single-detector gamma camera is a medical imaging device that uses gamma rays to produce images of the body. It consists of a detector, which is typically made of crystals such as sodium iodide or cesium iodide, and a collimator, which is a lead shield with small holes in it that allows only gamma rays coming from a specific direction to reach the detector. When a patient is injected with a radioactive tracer, the tracer emits gamma rays, which are detected by the gamma camera. The detector then converts the gamma rays into electrical signals, which are processed by a computer to produce an image of the area being examined. Single-detector gamma cameras are commonly used in nuclear medicine for a variety of diagnostic purposes, including detecting cancers, assessing organ function, and evaluating blood flow. They are also frequently used during surgery to help locate tumors and other abnormalities.
