Transient ischemic attack (TIA) is a common cerebrovascular disease, known as a 'minor stroke', and is an important warning signal for stroke. TIA is defined medically as a clinical symptom of focal neurological deficits caused by transient blood supply disorders to the brain, typically lasting within 1 hour, and with no evidence of acute cerebral infarction on imaging examinations. The treatment of TIA usually includes drug therapy, surgical treatment, and rehabilitation therapy. For non cardiogenic TIA patients, antiplatelet therapy is the cornerstone of acute phase drug therapy, and commonly used drugs include aspirin and clopidogrel. For TIA caused by cardioembolic embolism, anticoagulant therapy is the first choice, with representative drugs including warfarin, dabigatran, rivaroxaban, etc. For TIA patients with symptomatic carotid stenosis, carotid endarterectomy (CEA) and carotid artery stenting (CAS) are the main methods. Rehabilitation treatment includes blood pressure control, blood lipid regulation, blood glucose management, lifestyle intervention, and other aspects.
