## Abstracts

The global Transmissive Diffraction Gratings market size is expected to reach \$ million by 2029, rising at a market growth of % CAGR during the forecast period (2023-2029).

Transmission Gratings are a type of diffraction grating, which are optical elements that engrave many parallel, equidistant, and equal-width slits on transparent glass and use the principle of multi-slit diffraction to disperse the composite light.

The optical path design of Transmission Gratings is simple. For applications using fixed gratings, transmission gratings have obvious advantages, such as spectrometers. The incident beam is dispersed at a fixed angle at the back of the grating. Transmission gratings are insensitive to some types of grating alignment errors. In order to obtain high diffraction efficiency, the density of transmission grating lines is not high. The diffraction angle increases as the scribe density increases, and the refractive index of the base material limits the transmittance of long wavelengths, resulting in reduced performance. The dispersive properties of gratings make them suitable for compact systems using small detector arrays, and the gratings are also insensitive to polarization.

This report studies the global Transmissive Diffraction Gratings production, demand, key manufacturers, and key regions.

This report is a detailed and comprehensive analysis of the world market for Transmissive Diffraction Gratings, and provides market size (US\$ million) and Year-over-Year (YoY) Growth, considering 2022 as the base year.
