Cushing's disease in dogs, also known as hyperadrenocorticism, is a condition characterized by excessive production of cortisol, which can lead to various health issues. Common drugs include trilostane, which inhibits cortisol synthesis, and mitotane, which selectively destroys adrenal cortex cells.

The treatment of Cushing's disease in dogs has evolved significantly over the years, with a growing emphasis on targeted therapies and individualized care. Advances in veterinary medicine have led to the development of more effective and safer medications, such as trilostane and newer formulations of mitotane, which allow for better control of cortisol levels with fewer side effects. Additionally, the use of diagnostic imaging and hormone testing has improved the ability to accurately diagnose and monitor the disease. Researchers are also exploring novel therapies, including gene therapy and minimally invasive surgical options, indicating a trend toward more comprehensive and personalized approaches in managing this complex condition.
