Abstracts

The global Two-Legged and Four-Legged Robot market size is expected to reach \$ million by 2029, rising at a market growth of % CAGR during the forecast period (2023-2029).

Considerable attention has been focused on multi-legged robots, with progress being made in the areas of mechanical design, actuators, controls, planning, and learning-based methods. Legged robots are multi-input, multi-output, multi-end-effector systems. Hence, they are challenging to control when traversing unstructured environments. In recent years, technical progress has resulted in more real-world applications of legged robots.

Recent developments in the field of artificial intelligence (AI) have resulted in new opportunities for legged robots and have improved the coexistence and cooperation between legged robots and humans. Except for the direct deployment of general algorithms in AI, methods designed from the perspective of legged robotics have shown great potential to overcome some of the limitations in the field. Recent works have demonstrated that the high-dimensional complex dynamics of actuators and robotics can be modeled through deep neural networks, resulting in the learning of agile locomotion skills. Self-training in simulators with sim-to-real transfer learning is a new trend in legged robotics that can avoid excessive hardware consumption and experimental risks. Deep reinforcement learning and supervised learning methods have outperformed traditional approaches in actuator and locomotion control, and enable legged robots to autonomously traverse challenging natural terrains. In the future, data-efficient and generalized learning methods are needed for legged robots to accomplish more challenging tasks.

Four-legged robots, also called quadruped robots, are easier to build, program, and more stable and robust than two-legged robots. They are developed to traverse difficult terrain and use the alternating technique (in pairs) to walk. Quadrupedal robots exhibit quadrupedal motion and benefit from increased stability over bipedal robots, especially during movement. They also benefit from a lower center of gravity than two-legged systems.
