## Abstracts

According to our (Global Info Research) latest study, the global Wheel Hub Motors market size was valued at US\$ 12.43 million in 2025 and is forecast to a readjusted size of US\$ 107 million by 2032 with a CAGR of 29.8% during review period.

A wheel hub motors places the traction motor?optionally integrating the inverter/control electronics and braking-related interfaces?within the wheel hub or in-wheel package so that driving torque is generated directly at the wheel. By doing so, it can reduce conventional drivetrain components such as driveshafts and differentials, enabling independent wheel control and greater chassis packaging freedom.

The upstream supply base is primarily composed of electromagnetic and structural materials, bearing/sealing and brake-interface hardware, and power electronics.

The wheel hub motors market is still largely in the validation and low-volume adoption stage, with limited mass-production penetration today, but it is expected to enter a key ramp-up window during 2026?2028. In 2025, global wheel hub motors production reached approximately 8,000 units, with an average global market price is \$1,500 per unit.

Wheel hub motors are a key pathway toward distributed propulsion and a more electrified, software-coordinated chassis. The central idea is to place the traction motor at or near each wheel?sometimes directly within the wheel-end package?so each wheel can be driven independently with fast torque response. Beyond reducing mechanical drivetrain constraints, the strategic value lies in tighter coordination of propulsion with braking and chassis control, enabling finer traction and stability management and

offering new packaging freedoms that support low-floor layouts, improved space utilization, and platform modularity.

Technically, many in-wheel hub motor concepts use large-diameter, high-torque motor architectures suited to direct drive at the wheel end. The roadmap is moving toward highly integrated wheel-end drive units, where the motor is packaged closer to power conversion/control, sensing and diagnostics, and compatibility with friction braking and brake blending. High-performance approaches emphasize continuous power density and thermal robustness while still accommodating large performance brake hardware within conventional wheel and suspension envelopes. Commercial and specialty use cases prioritize durability, serviceability, modular replacement, and total cost of ownership. Overall, automotive hub motor are evolving from a 'motor-in-a-wheel' concept into a wheel-corner engineering discipline where hardware integration and software control are equally central.

The strongest application pull is typically found where packaging and control advantages outweigh engineering penalties: urban logistics and light commercial vehicles (flat floors and maximum cargo volume), specialty vehicles and autonomous delivery chassis (modularity and maintainability), and performance-oriented platforms that benefit from independent wheel torque control. In parallel, 'corner module' concepts are emerging, treating each wheel corner as an integrated functional unit that combines propulsion with braking/steering/suspension interfaces and control, accelerating multi-variant development and customization.

The barriers to mass adoption are clear. First, wheel hub motor integration tends to increase unsprung mass, which can negatively affect ride comfort, tire load variation, and handling precision, often requiring lightweight structures, suspension/damping retuning, and sometimes active or semi-active compensation. Second, the wheel-end environment is harsh (impact, debris, water, sand, salt, and temperature cycling), demanding robust sealing, corrosion protection, and shock resistance. Third, thermal management is more challenging due to limited space and complex heat paths, which can constrain continuous performance and long-term reliability. Fourth, system integration complexity rises across brake compatibility and blending, suspension/steering geometry effects, functional safety, and diagnostics?typically increasing validation cost and integration time. As a result, some corner-module approaches position the motor on the chassis side of the suspension (as sprung mass) to reduce ride and durability penalties while retaining modular architecture benefits.
