According to our (Global Info Research) latest study, the global Hybridization Buffer market size was valued at US\$ million in 2024 and is forecast to a readjusted size of USD million by 2031 with a CAGR of %during review period.

In this report, we will assess the current U.S. tariff framework alongside international policy adaptations, analyzing their effects on competitive market structures, regional economic dynamics, and supply chain resilience.

Molecular hybridization is a technique for determining the sequence of single stranded nucleic acid bases. The basic principle is to form detectable double helix fragments between the tested single stranded nucleic acid and a known sequence of single stranded nucleic acid (called a probe) through base pairing. Currently, solid-phase hybridization is widely used. This method involves first binding the single stranded nucleic acid sample to the membrane (if it is double stranded, it must be denatured into a single stranded), and then hybridizing it with the labeled probe in the solution. Hybrid buffer usually refers to a solution commonly used in molecular biology hybridization experiments. It is usually used to maintain a specific pH value and contains some specific salts to maintain the stability and activity of biological molecules (such as DNA, RNA, or proteins) during the experimental process.
