## Abstracts

According to our (Global Info Research) latest study, the global Pressurized Closed Loop Hot Water Boiler market size was valued at US\$ 3515 million in 2025 and is forecast to a readjusted size of US\$ 5415 million by 2032 with a CAGR of 6.3% during review period.

In 2025, approximately 96,470 new pressurized closed loop hot water boilers were installed globally, with a unit price of USD 35,410 and a gross profit margin of approximately 19%–33%. A pressurized closed loop hot water boiler is an industrial and civil heating device that operates in a closed pressurized system, uses liquid water as a circulating heat carrier, and continuously provides high-temperature heat energy of 110–200? to the water body by burning fuels such as natural gas or light oil. Its core consists of a pressurized furnace body, furnace shell and heat exchange tube bundle, low-NOx burner, circulating pump set, expansion and water replenishment device, safety valve and pressure interlock system, and flue gas and waste heat recovery module. The equipment avoids water vaporization at high temperatures by maintaining a system operating pressure of 0.7–1.6 MPa, and relies on multi-level temperature and pressure sensors, PLC/BMS group control and combustion safety management device to ensure stable pressure operation. The boiler body is typically made of Q245R/Q345R or Cr-Mo low-alloy steel. Key welds undergo RT/UT non-destructive testing to ensure pressure-bearing reliability. The heat exchange structure can be a three-pass wet-back, coiled, or flue + water pipe composite type to achieve a thermal efficiency of 87%–93% (up to 102% LHV for condensing boilers). Design priorities include pressure boundary stability, thermal inertia control, low NOx emissions (NOx ? 30 mg/Nm?), water corrosion prevention, and system circulation balance. It is mainly used in district heating stations, hospital energy centers, campus/commercial building heating, and industrial

process hot water applications in food processing, textiles, and chemicals. It is the core thermal unit connecting the heat source and load sides. Large hospital heating stations typically have 2–4 units in parallel; district heating stations commonly operate with 3–6 units in parallel.
