According to our (Global Info Research) latest study, the global Visible Filter market size was valued at US\$ million in 2024 and is forecast to a readjusted size of USD million by 2031 with a CAGR of %during review period.

Visible filter is a special glass material that increases the brightness of the image several times or dozens of times. Since the visible filter has a selective transmission effect on the wavelength of light, it can increase the clarity and color saturation of the image. In color TV, the use of this feature can enhance the vividness and layering of the image; in photography, it is used to eliminate noise, reduce contrast, and improve clarity.

The principle of the visible filter is: when the light passes through the visible filter, part of the light is reflected back and lost; the other part of the light enters the human eye through the visible filter and is absorbed by the photoreceptor cells. Since the human eye has the characteristic of selective absorption (that is, it is only sensitive to light in a certain wavelength range), the color perceived by the human eye after the visible filter is much brighter than the untreated color (because the Visible filter treated light is stronger than untreated light).
