A wireless surface electromyography (sEMG) system is a device used to detect electromyographic signals from the surface of human muscles. It primarily consists of surface electrodes, a signal acquisition module, a wireless transmission module, and a data processing unit. The surface electrodes are attached to the skin to collect the weak electrical signals generated during muscle activity. The signal acquisition module performs preliminary processing such as amplification and filtering on the signals obtained by the electrodes to enhance signal quality. The wireless transmission module sends the processed signals to the data processing unit in a wireless manner. The data processing unit, typically a computer or specialized data analysis device, is used for further analysis of the received signals, such as calculating muscle activation levels, fatigue states, and other related parameters.
