Checkpoint inhibitors for treating cancer is a type of drug that blocks certain proteins made by some types of immune system cells, such as T cells, and some cancer cells. These proteins help keep immune responses in check and can keep T cells from killing cancer cells. When these proteins are blocked, the "brakes" on the immune system are released and T cells are able to kill cancer cells better. Examples of checkpoint proteins found on T cells or cancer cells include PD-1/PD-L1 and CTLA-4/B7-1/B7-2. Those four kinds of checkpoint inhibitors are mainly used to treat melanoma, bladder cancer and others. In 2015, melanoma treatment consumed checkpoint inhibitors took a share of 80.53%. In 2016, melanoma treatment consumed checkpoint inhibitors will be 68153g. Bladder cancer treatment consumed checkpoint inhibitors will be 1978g.
