Demineralized bone matrix (DBM) is allograft bone that has had the inorganic mineral removed, leaving behind the organic 'collagen' matrix. It was first discovered by Marshall Urist in 1965 that the removal of the bone mineral exposes more biologically active bone morphogenetic proteins. These growth factors modulate the differentiation of progenitor cells into osteoprogenitor cells, which are responsible for bone and cartilage formation. As a result of the demineralization process, DBM is more biologically active than undemineralized bone grafts; conversely the mechanical properties are significantly diminished. The classification of demineralized bone matrix (DBM) includes gel, putty, putty with chips, and the proportion of Putty in 2017 is about 46%, and the proportion is in decreasing trend from 2013 to 2017. Demineralized bone matrix (DBM) is widely used in dental surgery, spine surgery, trauma surgery. The most proportion of demineralized bone matrix (DBM) is for spine surgery, and the proportion in 2017 is about 78%. North America is the largest consumption place, with a consumption market share nearly 56% in 2017. Following North America, Europe is the second largest consumption place with the consumption market share of 30%.
