Immune checkpoints are proteins that play an important role in regulating the immune system. In cancer, the immune checkpoints are activated to suppress the anti-tumor activity of the immune system thereby suppressing the immune response against the cancer cells. The study of these proteins and pathways has led to the development of a number of immune checkpoint inhibitors as therapies against cancer. Initial preclinical studies showed that antibody blockade of the immune checkpoint molecule CTLA-4 resulted in successful anti-tumor immune responses in the murine cancer models. This was then followed by studies targeting the PD-1/PD-L1 pathway. Ipilimumab and Yervoy were the first immune checkpoint inhibitors introduced in the market. With the promising results of Yervoy, several anti-PD-1 and anti-PD-L1 antibodies have been developed. Although there are number of other checkpoints that have been studied, such as LAG-3 and TIM-3, the only approved immune checkpoint inhibitors include CTLA-4, PD-1 and PD-L1.
