A vaccine is a biological preparation that improves immunity to a particular disease. A vaccine typically contains an agent that resembles a disease-causing microorganism, and is often made from weakened or killed forms of the microbe, its toxins or one of its surface proteins. The agent stimulates the body's immune system to recognize the agent as foreign, destroy it, and 'remember' it, so that the immune system can more easily recognize and destroy any of these microorganisms that it later encounters. Vaccines can be divided into recombinant vaccines, viral vaccines, polysaccharide vaccines and others. Recombinant vaccines and viral vaccines contain many kinds of vaccines, and the demand is larger than others kinds. But with the development of new technologies, more and more new types of vaccines will be popularized. The scope for disease prevention will be enlarged. The demand of other kinds is also increasing.
