REPORT SYNOPSIS

Atrial Fibrillation (AF) is the most common arrhythmia, which can lead to stroke, peripheral embolization, heart failure and other unfavorable outcomes. While the incidence of AF among the general population has been found to be at about 2.3%-3.4%, this registers a significant increase in patients with pulmonary disease, critical illness or systemic inflammatory response syndrome, with devastating clinical impact. A number of recent epidemiological studies have established a greater risk of AF and new-onset AF among patients with COVID-19, though the results have been quite inconsistent. The literature available thus far has indicated that AF or new-onset AF can have a substantial association with the worst outcomes, viz., mortality, in patients with COVID-19.

Apart from the recent development of COVID-19 and its effect on AF, other factors that increase the risk of this condition include growing worldwide prevalence of obesity and heart diseases. The rise in the number of AF cases is fueling the market for treating this disease, though at the same time posing a crushing burden on the economies of several countries because of the high treatment cost involved.
