### Report Synopsis

Several parameters are used for measuring Indoor Air Quality (IAQ), the most important of which comprise levels of carbon dioxide (CO<sub>2</sub>), relative humidity, volatile organic compounds (VOCs), particulate matter (PM<sub>2.5</sub> & PM<sub>10</sub>) and bioaerosols. While it is imperative that these be maintained within limits as prescribed by regulatory authorities, in most cases, achieving the same is next to impossible. Inadequate ventilation, ingress of external air along with pollutants and inadequate means of countering them result in growth of pollutants in indoor atmospheres, which, then, have to be dealt with by using other means.

The aforementioned approaches comprise the use of a vast variety of IAQ equipment available today, including Air Filters, Air Purifiers, Carbon Monoxide (CO) Detectors, Dehumidifiers, Humidifiers, Ultraviolet (UV) Lamps and Ventilation Systems, to name a few. The major areas where these systems are being deployed include Commercial Establishments, Industrial Operations and Residential Buildings, among which the latter comprises the largest and also the fastest growing area.
